

WORKING WITH ZFS SNAPSHOTS

> Solaris[™] 10 How-To Guides

Dominic Kay, Solaris Marketing Version 1.0 | Last updated: 01/05/09

About This Solaris[™] How-To Guide

This guide is intended to show a new user the capabilities of the ZFS snapshots feature. It describes the steps necessary to set up a ZFS filesystem and the use of snapshots including how to create them, use them for backup and restore purposes, and how to migrate them between systems. After reading this guide, the user will have a basic understanding of how snapshots can be integrated into system administration procedures.

ZFS Snapshots How-To Guide

ZFS Snapshots: Overview

A *zfs snapshot* is a read-only copy of a Solaris[¬] ZFS file system or volume. Snapshots can be created almost instantly and initially consume no additional disk space within the pool. They are a valuable tool both for system administrators needing to perform backups and other users who need to save the state of their file system at a particular point in time and possibly recreate it later on the same machine or some other. It is also possible to extract individual files from a snapshot. These tasks can be performed with ZFS without the need for any additional software. In this short guide, we take a look at the simple command syntax necessary to achieve these tasks.

Setting up the File System

1. First, we create a pool (which we call *pool*) and display it:

# zpool	. create -f pool c0d0s5					
# zpool	list					
NAME	SIZE	USED	AVAIL	CAP	HEALTH	ALTROOT
pool	3.11G	75K	3.11G	08	ONLINE	-

2. Then we create a file system (called file system) in our pool and confirm that we have done so:

<pre># zfs create pool/filesys # zfs list</pre>	create pool/filesystem				
NAME	USED	AVAIL	REFER	MOUNTPOINT	
pool/filesystem	18K	3.06G	18K	/pool/filesystem	

3. Now to illustrate our example we fill the file system with some data:

```
# cd /platform
# du -h -s.
 261M
# find . -print | cpio -pd /pool/filesystem
536032 blocks
# zfs list
NAME
                           USED
                                      AVAIL
                                                 REFER
                                                            MOUNTPOINT
pool
                           206M
                                      2.86G
                                                 19K
                                                            /pool
pool/filesystem
                           206M
                                      2.86G
                                                 206M
                                                            /pool/filesystem
```

We are now ready to start working with snapshots.

Taking and Using a Snapshot

Snapshots are named with the syntax pool/fs@something, where something can be a fairly arbitary name, but ideally
one that means something to the creator.

```
# zfs snapshot pool/filesystem@thursday
```

2. The snapshot is then visible using *zfs list*:

# zfs list				
NAME	USED	AVAIL	REFER	MOUNTPOINT
pool	262M	2.81G	19K	/pool
pool/filesystem	262M	2.81G	262M	/pool/filesystem
<pre>pool/filesystem@thursday</pre>	0	-	262M	-

3. However, the snapshot does not appear as a file system using df:

# df -h					
Filesystem	SIZE	USED	AVAIL	CAP	MOUNTED ON
pool	3.1G	19K	2.8G	1%	/pool
pool/filesystem	3.1G	262M	2.8G	98	/pool/filesystem

The reason it is hidden from normal Solaris utilities such as ls, tar, cpio, and others is to prevent the snapshot from appearing in backups.

Restoring From a Snapshot

1. Our snapshot can now be used as a recovery mechanism. First, we "accidentally" delete all the files in our file system:

```
# cd /pool/filesystem
# 1s
i86hvm i86pc
                i86xpv
# rm -rf *
# 1s
# df -h /pool/filesystem
Filesystem
                      SIZE
                                 USED
                                            AVAIL
                                                       CAP
                                                                MOUNTED ON
                                            2.8G
pool/filesystem
                      3.1G
                                 18K
                                                       1%
                                                                /pool/filesystem
```

We see that the files have been removed and the size of the data reported for our file system has decreased appropriately.

2. Rolling back the snapshot to restore all our missing files is trivial:

# zfs list					
NAME	USED	AVAIL	REFER	MOUNTPOINT	
pool	262M	2.81G	19K	/pool	
pool/filesystem	262M	2.81G	18K	/pool/filesystem	
pool/filesystem@thursday	262M	-	262M	-	
<pre># zfs rollback pool/files</pre>	system@thur	sday			
<pre># cd /pool/filesystem</pre>					
# 1s					
i86hvm i86pc i86xpv					
<pre># df -h /pool/filesystem</pre>					
Filesystem SIZE	E USE	D AVA	IL CAP	MOUNTED ON	
pool/filesystem 3.10	G 262	M 2.8	G 9%	/pool/filesystem	

We can see that the files have been returned and the space consumed again.

Restoring Individual Files

 It is possible to copy individual files from a snapshot by changing into the hidden .zfs directory of the pool that has been snapped:

```
# cd /pool
# ls -la
total 8
drwxr-xr-x 3 root
                                       3 Sep 11 15:33 .
                        root
drwxr-xr-x 23 root
                        root
                                    512 Sep 11 15:30 ..
drwxr-xr-x 2 root
                                       2 Sep 11 17:23 filesystem
                       root
# cd filesystem
# ls -la
total 6
drwxr-xr-x 2 root
                       root
                                       2 Sep 11 17:23 .
drwxr-xr-x 3 root
                       root
                                       3 Sep 11 15:33 ..
# cd .zfs
# 1s
snapshot
# cd snapshot
# 1s
thursday
# cd thursday
# 1s
i86hvm i86pc
                i86xpv
```

Moving the Snapshot to Another System

 You can move the snapshot to another system and install it there as a usable filesystem. First, create a pool to receive the snapshot on the target system:

otherhost#	zpool create -f otherpool c0d0s7					
otherhost#	zpool list	:				
NAME	SIZE	USED	AVAIL	CAP	HEALTH	ALTROOT
otherpool	6.22G	75K	6.22G	08	ONLINE	-

Then send the snapshot over the network and receive it into the pool using a combination of the ZFS send/receive commands and a network pipe:

```
# zfs send pool/filesystem@thursday | ssh otherhost "/usr/sbin/zfs receive
otherpool/myfs"
```

3. The received snapshot is then visible in the pool on the other host:

otherhost# zfs list				
NAME	USED	AVAIL	REFER	MOUNTPOINT
otherpool	262M	5.87G	19K	/otherpool
otherpool/myfs	262M	5.87G	262M	/otherpool/myfs
otherpool/myfs@thursday	0	-	262M	-

Archiving and Restoring Snapshots

Another use of snapshots is to create archives for long-term storage elsewhere.

1. In the following sequence of commands, we send the snapshot into a file and then compress it. It can then be retrieved from the file when required. This is also shown:

```
# zfs send pool/filesystem@thursday > /var/tmp/thursday.snap
# gzip -9 -v /var/tmp/thursday.snap
# zfs create pool/thursday
# gzip -d -c /var/tmp/thursday.snap.gz | zfs receive -F pool/thursday
```

For More Information

There is more to the use of ZFS snapshots that we have not covered in this brief treatment. More comprehensive coverage of both ZFS snapshots and clones, a related concept, are covered in the ZFS Administration Guide at Chapter 6: Working With ZFS Snapshots and Clones at http://docs.sun.com/app/docs/doc/819-5461. The Solaris ZFS manual is at http://docs.sun.com.
